

Eye Sample Noise Reduction Filters

Purposes:

- I. Reduction of high frequency noise from eye position data.
- II. Decreasing velocity and acceleration noise in the eye signal to aid in improved Eye Event Detection (Saccades, Fixations, Blinks).

Notes:

- I. The requirements of the experimental paradigm being used, and the need for real-time eye data signals, will often influence which Filtering algorithms can be used for a particular study.
- II. There is usually a trade-off between the number of data points required by a filtering algorithm / the computational complexity in performing the filter and the quality of the filtered output.
- III. An ideal filter would:
 - A. require few sample points per calculation, or require only previously collected data points when filtering the current point.
 - B. be computationally inexpensive (i.e. fast to calculate)
 - C. maintain real changes in eye signal positions, throughout the full biological oculomotor frequency range, while removing artificial signal fluctuations and artifacts.
- IV. I'm not aware of any filter that is /ideal/.

Common Code Snippets

Loading the 'Sample' data....

```

Example 1: Using Various Window Based Filters. SciPy.signal to the rescue....

Often Good Real-Time Filters

Two functions of particular relevance:

scipy.signal.filtfilt: Uses a given Window filter and passes forward and then backward through the data. This minimizes and phase shift caused by the filter, but also means it is only suitable for Post Hoc data filtering.

scipy.signal.lfilter: Uses a given Window filter in a forward pass only, so phase shift of the filtered data can occur, but this type of filtering operation can be used in real-time filtering situations.

See the [SciPy.signal Module docs](#) for a detailed list of all available filter types. Here we will only be comparing a couple.

A. Butterworth Filter

```

```

Example 2: [Savitzky Golay Smoothing Filter](#)

Good *Post Hoc* Filter

Quoting from wikipedia:

The Savitzky–Golay smoothing filter is a filter that essentially performs a local polynomial regression (of degree k) on a series of values (of at least $k+1$ points which are treated as being equally spaced in the series) to determine the smoothed value for each point. The main advantage of this approach is that it tends to preserve features of the distribution such as relative maxima, minima and width, which are usually 'flattened' by other adjacent averaging techniques (like moving averages, for example).

This filtering algorithm was first described in 1964 by [Abraham Savitzky](#) and [Marcel J. E. Golay](#).

Savitzky and Golay's paper is one of the most widely cited papers in the [journal Analytical Chemistry](#) and is classed by that journal as one of its "10 seminal papers" saying "it can be argued that the dawn of the computer-controlled analytical instrument can be traced to this article"

Python Implementation written by Dr. Thomas Haslwanter

[SciPy / Numpy implementation from the SciPy Cookbook](#)

```
In [11]: # SciPy / Numpy implementation from the SciPy Cookbook; recipe implemented by Thomas
# http://www.scipy.org/Cookbook/SavitzkyGolay

import numpy as np
import matplotlib.pyplot as plt

def savitzky_golay_1D(y, window_size, order, deriv=0, rate=1):
    r"""Smooth (and optionally differentiate) data with a Savitzky-Golay filter.
    The Savitzky-Golay filter removes high frequency noise from data.
    It has the advantage of preserving the original shape and
    features of the signal better than other types of filtering
    approaches, such as moving averages techniques.

    Parameters
    -----
    y : array_like, shape (N,)
        the values of the time history of the signal.
    window_size : int
        the length of the window. Must be an odd integer number.
    order : int
        the order of the polynomial used in the filtering.
        Must be less then `window_size` - 1.
    deriv: int
        the order of the derivative to compute (default = 0 means only smoothing)

    Returns
    -----
    ys : ndarray, shape (N)
        the smoothed signal (or it's n-th derivative).
    """
    import numpy as np
    from math import factorial
